Cork removing Device

ABSTRACT

A cork removing device for removing a cork from the neck of a bottle includes a pressure chamber, a hollow needle having a tip and extending from the pressure chamber for penetrating the cork longitudinally thereby presenting its tip to the interior of the bottle. There is a plunger for repeatedly diminishing the volume of the pressure chamber using a pumping action. A valve is situated between the pressure chamber and the hollow needle for allowing the flow of air from the pressure chamber to the bottle upon movement of the plunger theretoward and for preventing a back-flow of air from the needle to the pressure chamber. A handgrip attached to the plunger encases the pressure chamber when the volume of the pressure chamber is at a minimum.
